TECHNICAL Q&A ON C and EMBEDDED C

Q1. Difference between C and Embedded C ?

⇒ C - Programming :

- Used for general purpose applications, OS development, and software tools.
- Uses standard libraries (stdio.h, stdlib.h, etc).
- High portability across different hardware platforms.
- No direct access to hardware registers.

Embedded C :

- Designed for microcontrollers and embedded systems.
- Directly interacts with hardware (e.g., controlling GPIO, UART, I2C).
- Uses memory-mapped registers instead of standard libraries.
- Optimized for power efficiency and real-time constraints.

Example Code Comparison :-

- C Program (Standard Output) :

```
#include <stdio.h>
int main {
    printf ("Hello World! \n");
    return 0;
}.
```

- Embedded C Program (Microcontroller LED ON/OFF) :

```
#include < avr/io.h >
int main()[
    DDRB |= ( 1 << PB0); // Set PB0 as output
    PORTB |= ( 1 << PB0); // Turn ON led
    while (1);
    return 0;
}.
```

Q2. Volatile v/s Const in Embedded Systems :

⟹ Volatile :-

- Tells the compiler not to optimize the variable.
- Used when a variable's value can change unexpectedly (e.g., hardware registers, interrupt flags).
- Example :- Reading a sensor value that may change at anytime.

```
volatile int sensor_value ;
void read_sensor ()
{
  sensor_value = *(volatile int *) 0x40020000 ;
}.
```

↑ Read Sensor data

Const :-

- Declares a read-only variables whose value cannot change.
- Used for defining fixed value like baud rate, PI etc.
- Example :-

```
const int BAUD_RATE = 9600 ; // Fixed UART baud rate.
```

Key Difference :-

- Volatile prevents unwanted optimization.
- Const ensures a variable remains unmodifiable.

Q3. Pointers in Embedded Systems.

⟹ Defination :- A pointer is a variable that stores the memory address of another variable.

Uses in Embedded System :

- Accessing hardware registers.
- Implementing efficient memory management.
- Using function pointers for callback mechanisms.

- **Example** :- Direct register Access using Pointers.

```
#define GPIO_PORT *((volatile unsigned int *) 0x40020000)
void main ()
{
  GPIO_PORT = 0XFF ; // Turn ON all GPIO pins.
}.
```

Register Address

Function Pointers in Embedded Systems :-

- Used for ISR (Interrupt Service Routine) handlers.
- **Example** :-

```
void (*reset_func)(void) = (void (*) (void)) 0x00000000 ;
reset_func () ; // Jump to reset address
```

Assign reset vector

Q4. Stack v/s Heap in Embedded Systems :

⟹ **Stack** :-

- Stores local variable and function call information.
- Memory allocation is automatic (allocated and de-allocated by function calls).
- Fast access, but has a limited size.

Example :- `int a = 10 ; // stored in stack`

Heap :-

- Stores dynamically allocated memory.
- Memory allocation is manual (needs malloc() and free()).
- More flexible but slower than stack.

Example :-

```
int *ptr = (int *) malloc (sizeof (int)) ;
free (ptr) ;
```

Allocated in Heap

Prevent memory leak.

Issue in Embedded Systems :-

- Stack overflow occurs when recursion is used without a base conditions.

- Example :-

```
void recursive_function ()
{ recursive_function (); // no base case = stack overflow !
}.
```

Q5. UART, SPI and I2C in Embedded Systems.

⟹ UART (Universal Asynchrous Receiver - Transmitter) :-

- Asynchronous serial communication (no clock signal).
- Uses Tx (Transmit) and Rx (Receive) lines.
- Common baud rates : 9600, 115200 bps.
- Example :- UART_Write ('A') ; // sends character 'A'.

SPI (Serial Peripheral Interface) :-

- Synchronous serial communication (uses a clock signal).
- Uses 4 wires : MISO, MOSI, SCK, SS.
- Used in SD cards, sensors and flash memory.
- Example :- SPI_Write (0xAA) ; // sending data to SPI device

I2C (Inter - Integrated Circuit) :-

- Uses only 2 wires : SDA (Data) and SCL (Clock).
- Supports multiple slave address.
- Used in temperature sensors, EEPROMs and RTCs.
- Example :-

```
I2C_Start ();
I2C_Write (0x50) ; // sends device address.
```

Q6. CAN Protocol in Automotive ?

⇒ A message based protocol used in automotive and industrial applications.

- Support multi-master communication.
- Provides error detection and fault tolerance.

Features :-

- Priority-based arbitration (higher priority messages get access first).
- Supports multiple nodes on a single bus.
- Real-time performance (fast response in vehicle control systems).

Example :- CAN message Transmission in C :

```
CAN_Transmit (messageID, data, length);
```

Q7. RTOS v/s General OS :-

⇒ RTOS (Real-Time Operating System):-

- Used in automotive ECUs, industrial automation, and medical devices.
- Provides deterministic task scheduling (guranteed execution time.
- Low latency for real-time applications.

Example RTOS Task Creation :-

```
xTaskCreate (Task1, "Task1", 100, NULL, 1, NULL);
```

General OS (Windows, Linux, etc) :-

- Used for general computing tasks.
- Non-deterministic scheduling (task execution order is unpredictable).
- Designed for user applications like web-browsing, gaming and office work.

Q8. Debugging tools in Embedded Systems.

⇒ • GDB (GNU Debugger) :- Used for debugging C programs in Linux.

• CANoe :- Used for testing and debugging CAN protocol based applications.

• SonarQube :- Used for code quality analysis and bug detection.

Q9. Code optimization in Embedded Systems :

⇒ • Use Bitwise Operations instead of Arithmetic :

• #define SET_BIT (PORT, BIT) (PORT |= (1 << BIT))

↑

Faster than arithmetic

• Reduce function calls and loops to save execution time.

• Use static, const to optimize memory usage.

• Enable compiler optimization flags (-O2, -O3).

Q10. Difference between macro and inline function ?

⇒

Features	Macro	Inline Function
1) Defination	#define SQUARE(x) (x*x)	static inline int square (int x) { return x * x ; }.
2) Type safety	No type checking.	Type-safe.
3) Debugging	Hard to debug.	Easier to debug.
4) Performance	Faster (avoids function call overhead.	Slightly slower but safer.

Final Thoughts :- These are the technical concepts you must master before your Embedded Developer or C Developer interview.
