ABOUT OS

ABOUT OS:

-> OS stands for "OPERATING SYSTEM".

->Interface between Software and Hardware is called "OS".

Without OS our system can be work are not? why?

Without an Operating System (OS), a computer can power on, but it cannot perform normal OS-based tasks like running Windows applications, managing files, or providing a desktop interface.

What happens without an OS?

1. Power ON: The computer can receive power and start.

2. BIOS/UEFI: Firmware initializes the hardware.

3. Booting: Normally, the computer loads an operating system.

4. Without an OS: The computer cannot start a normal OS-based environment, but it may run firmware or a bare-metal program.

Example

Suppose you have a laptop.

With an OS:

- You can open applications.

- You can create and save files.

- You can browse the internet.

- You can run multiple programs.

Without an OS:

- The laptop can power on.

- BIOS/UEFI can still run.

- Normal desktop applications cannot run directly.

- Special programs can still run directly on hardware.

Why do we need an Operating System (OS)?

->processor management

->Multitasking

->Sheduling

->memory management

Based on the hardware behaviour Linux will classify the hardware 5 types:

1.**RAM:** page information.

2.**CPU:** exicuited the instructions.

3.character devices: byte by byte.

4.storage block device: block by block.

5.Networking devices: packet by packet.

They are 2 types of memory:

1.primary memory.

2.secondary memory.

Primary memory: all applications executed in the primary memory.

Secondary memory: All applications installed in the secondary memory.
